Atlas of Skin Pathology (Current Histopathology) R.M. Marks, A.G. Knight, P. Laidler

Dermatopathology is both exciting and exasperating. The stratum corneum is composed of keratinized cells. This occurs in disorders of keratinization. Skin has an elegant simplicity in its functions yet a tremendous complexity because the process of desquamation is disturbed (Figure 1. 1). The tremendous complexity in its structure. This is one of the paradoxes that underlie the pathology of skin disease. Parakeratosis. The presence of nucleated horn cells in and may go some way in explaining the multilaminar stratum corneum. Normally the horn cells (keratinocytes) to which the skin is subject. The readily visible ones are thin lamellae of less than 1 μ m thickness. They of the skin may also help explain why straightforward contain no detectable cytoplasmic contents as these are histological examination cannot always provide an answer in the granular cell layer. Parakeratosis occurs when answer to a clinician's question. Quite dramatic appear the process of keratinization is disturbed such as when anec may be due to alterations of the relative rates of the rate of epidermal cell production is increased (as in blood flow, with or without oedema, in the different psoriasis) so that nuclei are not broken down before the vascular plexuses or around different structures in the stratum corneum is reached and when damage occurs horizontal dimension, neither of which may result in to the upper epidermis (Figure 1. 2). 'much to see' histologically. The inherent sampling error Parakeratosis.
